Applications of Reinforcement Learning in Real World

There is no reasoning, no process of inference or comparison; there is no thinking about things, no putting two and two together; there are no ideas — the animal does not think of the box or of the food or of the act he is to perform. — — Edward Thorndike(1874–1949), the psychologist who proposed Law of effect.

Deep Reinforcement Learning: Pong from Pixels

May 31, 2016

This is a long overdue blog post on Reinforcement Learning (RL). RL is hot! You may have noticed that computers can now automatically [learn to play ATARI games](#) (from raw game pixels!), they are beating world champions at [Go](#), simulated quadrupeds are learning to [run and leap](#), and robots are learning how to perform [complex manipulation tasks](#) that defy explicit programming. It turns out that all of these advances fall under the umbrella of RL research. I also became interested in RL myself over the last ~year: I worked [through Richard Sutton's book](#), read through [David Silver's course](#), watched [John Schulmann's lectures](#), wrote an [RL library in Javascript](#), over the summer interned at DeepMind working in the DeepRL group, and most recently pitched in a little with the design/development of [OpenAI Gym](#), a new RL benchmarking toolkit. So I've certainly been on this funwagon for at least a year but until now I haven't gotten around to writing up a short post on why RL is a big deal, what it's about, how it all developed and where it might be going.

Examples of RL in the wild. **From left to right:** Deep Q Learning network playing ATARI, AlphaGo, Berkeley robot stacking Legos, physically-simulated quadruped leaping over terrain.

REINFORCEMENT LEARNING (DQN) TUTORIAL

Author: Adam Paszke

This tutorial shows how to use PyTorch to train a Deep Q Learning (DQN) agent on the CartPole-v0 task from the [OpenAI Gym](#).

Task

The agent has to decide between two actions - moving the cart left or right - so that the pole attached to it stays upright. You can find an official leaderboard with various algorithms and visualizations at the [Gym website](#).

https://pytorch.org/tutorials/intermediate/reinforcement_q_learning.html

Code is available

Reinforcement Learning: Introduction to Monte Carlo Learning using the OpenAI Gym Toolkit

ANKIT CHOUDHARY, NOVEMBER 19, 2018

[LOGIN TO BOOKMARK THIS ARTICLE](#)

Monte Carlo Implementation in Python

Frozen Lake Environment

The agent controls the movement of a character in a grid world. Some tiles of the grid are walkable, and others lead to the agent falling into the water. Additionally, the movement direction of the agent is uncertain and only partially depends on the chosen direction. The agent is rewarded for finding a walkable path to a goal tile.

The surface is described using a grid like the following:

S	F	F	F
F	H	F	H
F	F	F	H
H	F	F	G

(S: starting point, safe), (F: frozen surface, safe), (H: hole, fall to your doom), (G: goal)

Monte Carlo Methods – An Example

Any method which solves a problem by generating suitable random numbers, and observing that fraction of numbers obeying some property or properties, can be classified as a Monte Carlo method.

Let's do a fun exercise where we will try to find out the value of pi using pen and paper. Let's draw a square of unit length and draw a quarter circle with unit length radius. Now, we have a helper bot C3PO with us. It is tasked with putting as many dots as possible on the square randomly 3,000 times, resulting in the following figure:

C3PO needs to count each time it puts a dot inside a circle. So, the value of pi will be given by:

$$pi = 4 * \frac{N}{3000}$$

Code is available

Q-LEARNING ALGORITHM

Q-learning is a model-free reinforcement learning algorithm. The goal of Q-learning is to learn a policy, which tells an agent what action to take under what circumstances.

```
define epsilon, alpha, gamma
initiate Q-table with zeros
observe initial state s
repeat:
    select an action a
        with probability  $\epsilon$  select random action a
        else select action  $a = \text{argmax}(Q(s, a'))$ 
    carry out action a
    observe next state  $s'$  and reward r
    calculate  $Q\_target = r + \gamma \max[Q(s', A)]$ 
    Calculate  $Q\_delta = Q\_target - Q(s, a)$ 
    add  $\alpha * Q\_delta$  to  $Q(s, a)$ 
     $s = s'$ 
until terminated
```

GRID WORLD EXAMPLE

Environment 5*5 grid - Each cell represent the state the agent can be in.

Agent

4 actions: Moving step will give us a reward of -0.04.

Trap: Red square will give us a reward of -1.

Target: Green square will give us a reward of +1.

LET SEE THE CODE

The screenshot shows a Jupyter Notebook interface. At the top, the Jupyter logo is followed by the text "jupyter Untitled Last Checkpoint: Last Sunday at 11:04 PM (unsaved changes)". To the right of this is a Python logo and a "Logout" button. Below this is a menu bar with "File", "Edit", "View", "Insert", "Cell", "Kernel", "Widgets", and "Help". To the right of the menu bar are "Trusted" and "Python 3" indicators. Below the menu bar is a toolbar with icons for saving, adding, deleting, and running cells, as well as a "Markdown" dropdown menu. The main content area of the notebook contains a code cell with the following text:

```
In [*]: 1 import world
        2 import threading
        3 import time

In [*]: 1 # parameter to discount future rewards
        2 discount = 0.3
        3 # actions = ['up', 'down', 'left', 'right']
        4 actions = World.actions
        5 # Each cell represent the state the agent can be in. Matrix[5*5]
        6 states = []
        7
        8 for i in range(World.x):
        9     for j in range(World.y):
        10         states.append((i, j))
        11
        12 for state in states:
        13     temp = {}
        14     for action in actions:
```

THANK YOU!
